01 Project Overview

This report summarizes a Python-driven analysis of customer support tickets aimed at uncovering common issues, classifying priorities, and generating actionable insights. Text preprocessing — including lowercasing, punctuation removal, and format standardization — was applied before analysis to ensure data consistency and improve result accuracy.

02 Priority Distribution

High- and low-priority tickets occurred with equal frequency (6 each), jointly comprising 75% of total volume. Medium-priority issues were the least frequent, suggesting a polarized customer experience with relatively few issues falling in between.

03 Longest Issue Descriptions

Ticket 2
Meera

"slow response very poor service"

Ticket 7 Arjun	"good support and good behavior"
Ticket 8 Kiran	"poor handling of technical issue"
Ticket 16 Sukanya	"website is not loading properly"

Three of the four longest descriptions reflect pain points around service speed, technical handling, and website availability. The inclusion of a positive entry from Arjun highlights that exceptional service experiences also exist within the dataset.

04 Unique Word Analysis

poor	slow	bad	freezing	unable	issue	technical	not	loading
good	excellent	great	helpful	satisfied	quick	resolved		
support	service	response	website	mobile	booking	handling		

Red tags = Negative sentiment **Green tags** = Positive sentiment **Blue tags** = Neutral / Topic words

A total of 46 unique words were identified. Negative terms around slowness, technical failures, and poor handling dominated, while positive terms such as 'excellent', 'great', and 'resolved' indicate a meaningful proportion of satisfactory interactions. Core service touchpoints — 'support', 'service', 'response' — appeared across both sentiment clusters.

05 Key Findings & Conclusion

- Response speed is the top concern — 'slow' and 'response' were among the highest-frequency terms, pointing to service latency as the primary driver of complaints.
- Technical reliability requires attention — issues such as website loading failures, mobile app freezing, and report download errors were reported by multiple customers.
- Positive sentiment exists but outnumbered — words like 'excellent', 'great', and 'helpful' confirm satisfactory service pockets worth replicating at scale.
- Data preprocessing improved analysis accuracy — standardized text led to cleaner word-frequency results and more reliable insight extraction.

The analysis highlights two core challenges: slow response times and recurring technical issues. Addressing these — alongside scaling the positive service experiences already present — will significantly improve customer satisfaction. Future work with larger datasets and sentiment scoring can further sharpen these insights.
